

1 **TITLE: NOSE AIRWAY DEVICE FOR DETECTING AIRBORNE CONTAMINANTS**

2 **INVENTOR: H. GEORGE BRENNAN**

3 **DOCKET NO.: 01BRE1**

4 **SPECIFICATION**

6 **BACKGROUND OF THE INVENTION**

7 1. **Field of the Invention**

8 This invention relates to a device adapted for temporary insertion within the nose for
9 establishing and/or maintaining an airway through the nasal passages and for detecting the
10 presence of noxious airborne substances.

12 2. **Description of the Prior Art**

13 Various forms of nasal airway devices are known in the art. Examples of such devices
14 are disclosed in the following U.S. Patents: 851,048; 513,458, 4,414,977; 4,201,207;
15 2,515,756; 1,255,578; 1,481,581; 1,597,331; 1,672,591; 1,709,740; 1,135,675; 1,014,076;
16 1,014,758; 1,077,574 and British Patent GB0768488; British Patent 4,148; Italian Patent
17 IT0490828 and French Patent 7807130. While most of these devices provide a means for
18 dilating the nostrils and maintaining an airway permitting improved air flow therethrough,
19 each has limitations producing less than optimum air flow or discomfort which prevents the
20 device from being used for a prolonged period of time. Many devices are unsatisfactory due
21 to non-unitary construction which can result in situ disintegration of the device and possible
22 aspiration of a fragment of the device. The above devices do not have or teach the structural
23 and functional features of the present invention described below which, in combination, enable
24 the device to perform the intended function in a manner which is superior to the prior art
25 devices. In particular, none of the prior art nasal airway devices include means operable for
26 indicating the presence of an airborne contaminant entering the nasal passages.

1 The potential for human exposure to dangerous concentrations of noxious airborne
2 contaminants such as anthrax spores has increased dramatically in recent months due to the
3 introduction of pathogenic organisms into the work environment by deliberate criminal intent.
4 Exposure to airborne contaminants such as anthrax spores and sarin gas is highly probable in
5 the future, particularly for members of the military engaged in hostile action. In the case of
6 anthrax, it is imperative that detection means operable for early detection of such human
7 exposure to the airborne pathogen be available to both civilian and military populations.
8 Ideally, such a detection system provides an indication and measure of an individual's
9 exposure to a particular contaminant so that only individuals who have received a dangerously
10 high level of exposure receive preemptive treatment. Accordingly, a detection device adapted
11 to be worn upon the body and disposed to sample air that is actually inhaled by an individual
12 is particularly desirable.

14 SUMMARY OF THE INVENTION

15 It is a primary object of this invention to provide an intranasal device for
16 sampling air delivered to the respiration passages and providing an indication of exposure to
17 dangerous levels of contaminants in the air.

18 It is a further object of this invention to provide a device meeting the above objective
19 and adapted to be comfortably attached to a person's nose, thereafter being operable for
20 increasing the flow of air through the nasal passages during periods of physical activity
21 requiring high oxygen demand or increased ventilation.

22 It is another object of this invention to provide a device meeting the above objectives
23 and which includes a means for controlling and/or limiting the projection of the device into the
24 nostrils while preventing the device from dislodging and being ejected from the nostril.

25 It is another object of this invention to provide a device which meets the objectives
26 stated above and which can be easily and inexpensively manufactured by injection molding

1 from an inexpensive hypoallergenic plastic composite, copolymer or elastomer coated plastic
2 in a variety of sizes.

3 The above objects and advantages of the present invention are accomplished by the
4 present nasal airway airborne contaminant indicator device. In a particularly preferred
5 embodiment of an airborne contaminant indicator device in accordance with the present
6 invention, the proximal dilating portion of the device comprises two "U" shaped surfaces
7 adapted to be inserted into the nostrils. The dilating portion of the device is inter-connected by
8 means of a bridging "U" shaped extension portion. The extension portion is a generally "U"
9 shaped having a semicylindrical wall with an inner circumferential surface which is contoured
10 to anatomically and snugly conform to the inferior (most distal) margin of the nasal septum.
11 Thus, overall the device is generally "U" shaped, more or less resembling a cotter pin when
12 viewed in front elevation and "U=U" shaped when the proximal portion is viewed end on
13 from the top. The bifurcated extension portion comprises two identical substantially planar
14 parallel strips oriented with their flat surfaces in parallel planes and connected to one another
15 by the semicylindrical distal septum attachment portion. The symmetrical dilating portion is
16 contoured to anatomically conform to the respective contours of the anterior inner surface of
17 the nostrils. Since inhaled air flowing through the nose contacts the inner surfaces of the
18 "U's", a contaminant-adsorbing coating, applied thereto, that is operable for removing at least
19 a portion of the contaminants, including particulates, from the airflow, is employed to provide
20 evidence of the wearer's exposure to selected airborne contaminants

21 The features of the invention believed to be novel are set forth with particularity in the
22 appended claims. However, the invention itself, both as to organization and method of
23 operation, together with further objects and advantages thereof may best be understood by
24 reference to the following description of a preferred embodiment of the invention, taken in
25 conjunction with the accompanying drawings in which:

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a front elevational view of a particularly preferred embodiment of an airborne contaminant indicating device in accordance with the present invention.

Figure 2 is a perspective view of the airborne contaminant indicating device shown in Figure 1.

Figure 3 is a side view of the airborne contaminant indicating device of Figure 2 viewed in the direction of line 3-3'.

Figure 4 is a perspective inferior view of the airborne contaminant indicating device in accordance with the present invention positioned within the nose of a person and illustrating the disposition of the contaminant-sensitive coating with respect to the nasal airway passages.

Figure 5 is a schematic lateral view of the airborne contaminant indicating device positioned within the nose which has been partially cut-a-way for illustration.

Figure 6 is a perspective view of an embodiment of the invention having gripping pins adapted for facilitating instrument assisted insertion of the airborne contaminant indicating device into the nose.

Figure 7 shows the cooperative functional relationship between the insertion instrument and the airborne contaminant indicating device of Figure 6 prior to insertion of the device into the nose.

Figure 8 is an elevational view of the airborne contaminant indicating device of Figure 6 looking upward into the nose with the device properly positioned for operation and illustrating the trapping of particulate contaminants in the air by a cilia-like coating on a portion of the device.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

The airborne contaminant indicating device 10, shown in front (anterior) elevational view in Figure 1, is a unitary strip of elastically deformable material, preferably

1 hypoallergenic, elastomer shaped to form a symmetrical 3-dimensional structure as generally
2 shown in Figure 2. The airborne contaminant indicating device 10 is bifurcated and
3 symmetrically disposed in structure with respect to the medial septum attachment portion 11.
4 The septum attachment portion 11 is a semi-cylindrical arcuate distal coterminous for the
5 inferior or distal end of the extension portion 14 and 14' of the device 10, connecting the tines
6 14 and 14' of the extension portion to one another and having an inner diameter D. The
7 extension portion consists of tines 14 and 14' and extends proximally, away from the septum
8 attachment portion a distance L, the proximal terminus of the extension portions 14, 14' being
9 shown at 15. The dilating portion consists of two "U" shaped projections projecting
10 anteriorly on a plane at right angles to the extension portion 14, to gracefully and arcuately
11 curve laterally outward and posteriorly to form smooth, anatomically conforming tissue-
12 contacting surfaces 13 and 13' which are mirror images of each other. The side of the dilating
13 portions opposite the tissue contacting surfaces 13 and 13' are coated with a material that
14 interacts with airborne contaminants in such a way as to enable the device to be used for
15 determining exposure to one or more airborne contaminants. The extension portion 14 and 14'
16 preferably be a length L between 1/2 inch and 1 inch. The width W of the device 10 is
17 substantially uniform throughout the device and preferably in the range of 1/8-.5/16 inches.
18 The thickness of the device, excluding the thickness of the contaminant adsorbing coating 43,
19 is also substantially uniform throughout and preferably less than 1/16 of an inch.

20 The device may be positioned within the nose 40 (Figure 4) by inserting the proximal
21 end 15 of the airborne contaminant indicating device 10 into the nasal air passages 42 and
22 advanced by applying pressure on the distal opposing end until the distal septum attachment
23 portion 11 is in contact with the inferior margin of the nasal septum 41. At this point, the
24 proximal end 15 of the device 10 can be advanced no further into the nasal passages 42 and the
25 anatomically conforming tissue-contacting surfaces 13 and 13' comprising the dilating portion
26 press laterally against the anterior and lateral wall of the nasal passage to dilate the passage

1 and maintain an airway therethrough. A contaminant interactive coating 43 disposed on the
2 inner surface (i.e., the surfaces opposite the tissue-contacting surfaces 13 and 13') of the
3 dilating portion of the airborne contaminant indicating device 10 interacts with airborne
4 contaminants in such a way as to provide an indication that a contaminant is, or was, present in
5 the airflow stream during periods of use. A coating 43 may, for example, have numerous cilia-
6 like filaments extending into the airstream. Such a filamentous coating 43 extracts particulates
7 (not shown in Figure 4) from the airstream and concentrates the contaminants between the
8 filaments. The coating 43 may, for example, be a material that releases the particulate
9 contaminant accumulated thereon for assaying or other investigative purposes after treatment
10 with an appropriate reagent, or provide a colorimetric indication of the presence of a particular
11 airborne contaminant in contact therewith either with or without treatment by suitable
12 indicator reagents.

13 The above-described embodiment is shown in Figure 5 wherein the airborne
14 contaminant indicating device 10 is seen to be comfortably positioned within the (partially
15 sectioned) nose 40 of the patient. The surfaces 13 and 13' elastically urge outward to press
16 laterally outward against the wall of the nasal passage and provide a smooth, non-irritating
17 tissue-contacting surface for comfort. The anterior projection 12' of the dilating portion is
18 shown facing the front or anterior portion 51 of the nose 40 and the septum attachment portion
19 11 is releasably attached to the inferior margin 41 of the nasal septum by medially directed
20 elastic restorative forces.

21 Figure 6 is a perspective view of an embodiment of the airborne contaminant
22 indicating device 10 including gripping pins 61 adapted to be grasped by an instrument 62 for
23 facilitating instrument assisted insertion of the device 10 into the nose. The airborne
24 contaminant interactive coating 43 is applied to a portion of the surface of the device 10 so as
25 to contact air flowing through the nose. Figure 7 shows the cooperative functional relationship
26 between the insertion instrument 62 and device 10 prior to insertion of the device into the

1 nose. The tines 14 and 14' of the extension portion of the device are urged toward one another
2 in the direction indicated by the broad arrows in Figure 7 and the proximal end 15 inserted into
3 the person's anterior nasal passages and advanced therein by means of the instrument 62.
4 When the pressure exerted by the instrument 62 on the pins 61 is released, the tines of the
5 extension portion bear against the lateral tissue surfaces of the medial nasal septum to stabilize
6 the device while the proximal arcuate tissue-contacting surfaces of the dilating portion buttress
7 a portion of the inner perimeter of the nasal passages, urging the tissue in contact therewith
8 radially outward to create and maintain symmetrically disposed open nasal airways.

9 Figure 8 is an elevational view looking upward into the nose 40 showing the airborne
10 contaminant indicating device 10 properly positioned in accordance with this invention for
11 maintaining an open airway within the nose, while presenting an interactive surface 43 to
12 adsorb airborne contaminants 81 entrained in the air stream passing thereover. The airborne
13 contaminant interactive coating 43, which may be a contaminant-specific adsorptive or
14 reactive coating, may be affixed to the outer surface 80 (i.e., the surface in opposition to tissue
15 contacting surface 13 and 13') of the dilating portion of the airborne contaminant indicating
16 device 10 to adsorb or chemically react with airborne contaminants 81 entrained in the air
17 stream. Figure 8 shows a portion 81' of the airborne contaminants 81 trapped in a lattice
18 provided by a cilia-like coating 43. In addition to the present invention's utility for
19 maintaining an airway and indicating exposure to an airborne contaminant, the tissue-
20 contacting surfaces 13 and 13' of the device may be open cell or porous and permeated with a
21 medicament that is released into the tissue in contact therewith.

22 A preferred method for providing a contaminant indicating coating 43 comprises the
23 application of a thin film of an adsorbant or chemically reactive reagent or a hydrogel or
24 silicone gel coating containing an indicator reagent that provides, or can be further treated to
25 provide, an indication of exposure to an airborne contaminant to the surface 80 of the airborne
26 contaminant indicating device 10 to form coating 43 thereon. After use, the coated surface 43

1 of the device can be either visually inspected to indicate exposure to an airborne contaminant,
2 or the coating may be further treated by a visualizing reagent as, for example, in a home test
3 kit, to provide an indication of the exposure of the coated surface 43 to an airborne
4 contaminant. In a particularly preferred embodiment, the coating 43 comprises a layer of
5 synthetic polymer having fibrils or a tortuous surface projecting into the air stream. After use,
6 at the end of a day, for example, the device 10 can be removed from the nose and treated by
7 immersing the coating 43 in a solvent that will dissolve the fibrils and release the particulate
8 contaminants, entrapped and accumulated therein, into the solvent. The solvent containing the
9 contaminants in suspension can be mounted on a slide for microscopic examination, cultured,
10 or otherwise analyzed for detection of the presence of, and the determination of the amount of,
11 a contaminant, such as, for example, anthrax spores, that may be injurious to health. In
12 addition, a test kit may be used in a home environment for providing a visual indication, such
13 as a color change, of exposure of the coating 43 to an airborne contaminant. Appropriate
14 medicaments such as, for example, antibiotics exhibiting a therapeutic effect may then be
15 timely administered to the patient if a high level of exposure to a particular contaminant is
16 indicated.

17 While particular embodiments of the present invention have been illustrated and
18 described, it would be obvious to those skilled in the art that various other changes and
19 modifications can be made without departing from the spirit and scope of the invention. For
20 example, the airborne contaminant indicating device 10 is applicable, or may be adapted to
21 concentrate and/or detect any number of different airborne contaminants, the particular
22 contaminants detected depending on the specificity of the coating 43. Further, while a
23 particular embodiment of an airway device that is suitable for supporting a contaminant
24 sensitive or adsorbant coating within the nose and present the coating to the air stream passing
25 through the nose, has been described, the particular device 10 is intended to provide a
26 preferred exemplar of the invention. Many other possible geometries are possible for the
